Core Networking Panel

*

Sally Floyd January 9, 2003 NSF ANIR Principle Investigator Meeting

With input from members of the End-to-end Research Group, and with material "borrowed" from Craig Partridge, Dave Rossetti, and others.

#1: Progress in Core Networking Research Areas?

*

- There is a great need for further research on core networking.
- We can't rely on industry for all of the research in core networking.
- Research is needed on the evolution of the Internet infrastructure as well as on longer-time-scale grand challenges.
- A key consideration for NSF:

– Whether the research is science (e.g., contributing to our body of knowledge of networking) as well as engineering (the practical application of that knowledge).

 This includes the body of knowledge about the human-created complex system of the global Internet.

#1: The Need for Further Research in Routing:

*

Smaller issues:

- Convergence.
- Multimetric routing (e.g., with both hop-count and delay as metrics).
- How do users choose the ISPs that their packets will traverse?

Larger and longer-time-scale issues:

- What replaces BGP?
- How do routing algorithms deal with intermittent connectivity, scheduled connectivity, and unidirectional links.

#1: The Need for Further Research in Transport:

*

Smaller issues:

- Transport-level congestion control mechanisms:
- Multicast as well as unicast.
- Congestion control for streaming media or for other applications.
- Congestion control for very-high-speed or high delay environments.

Larger and longer-time-scale issues:

- Congestion control mechanisms in routers:
 - Responding to aggregates such as DDoS attacks.
 - More fine-grained feedback from routers?
- New forms of communication between layers?
- Understanding global dynamics.

• ...

#2: The Evolution of the Internet?

*

- We need a more scientific understanding of the evolutionary potentials and difficulties of the Internet infrastructure:
 - of the inherent forces and dynamics of evolution;
 - of the past difficulties and successes;
 - of the future range of possibilities.
- We don't want to give up on the evolutionary development of the Internet infrastructure just because it is harder than it used to be ... where that is the appropriate path.

#2: Overlay Networks:

*

- Overlay networks are a great transition technology.
- Capabilities from overlay networks should move into the core if:
 - they have an inherent need to be everywhere;
 - there are scaling issues;
 - they are general purpose and widely useful.

#3: The challenges of scalability, manageability, robustness, and more:

*

- The Internet architecture gives a reasonably sound foundation (though not perfect):
 - We don't want to start again from scratch, unnecessarily.

- The best track records so far have come from combining architecture and analysis with a deeply empirical approach.

• At the same time, the scalability, manageability, and robustness of the Internet are at risk.

#3: Revisiting the core problems in this context:

*

- We could start by understanding better:
 - the current scaling limits;
 - the new stresses from the environment;
 - the tradeoffs between complexity and robustness;
 - the challenges of manageability;

 how to add robustness in terms of robust performance in known extreme environments, without sacrificing robustness in unforseen circumstances.

— ...

• We probably also have to explore a range of new directions.
