

The probability that the client can connect after  $k$  tries is:

$$\begin{aligned} P(\text{connect after } k \text{ tries}) \\ &= 1 - (1 - P(\text{connect after 1 try}))^k \\ &= 1 - (1 - (1 - \epsilon_i)^i)^k \end{aligned}$$

the required number of connection attempts is:

$$k = \frac{\log(1 - P(\text{connect}))}{\log(1 - (1 - \epsilon_i)^i)}$$

A nice feature of this formula is that the expected number of connection attempts depends logarithmically on the connection probability, which indicates that even for large  $\epsilon_i$ , a determined client can get a connection after a moderate waiting time.

## Attack Mitigation Techniques

# July 4<sup>th</sup> DDoS Attack Timeline

## Multi-Phased Attack

### 1<sup>st</sup> Wave of Elevated Traffic

- 1 Day Duration
- 7.4 Billion Total Page Views
- 192.5 TB Served
- Equal 12 OC-192's & 2,500 Servers
- 99.9% BW, 96.2% Request Offload

### Subsequent Waves of Elev Traffic

- Next 3 Days of Attack
- 726.6 Million Total Page Views
- 42.2 TB Served

"The first list had only five targets — all U.S. government sites. A second list used by the malware on July 6 had 21 targets, all U.S. government and commercial sector sites, including e-commerce and media sites. A list on the 7th switched out some of the U.S. sites for ones in South Korea. ...- Joe Stewart, director of malware research at SecureWorks
